ABSTRACT
The emphasis on participation in social technologies challenges some of our traditional assumptions about the role of users and designers in design. It also exposes some of the limitations and assumptions about design embedded in our traditional models and methods. Based on a review of emerging practice we present four perspectives on design in the context of social technologies. By presenting this ‘lay of the land’, we seek to contribute to ongoing work on the nature of participation and design in the context of social technologies. We draw particular attention to the ways in which roles and responsibilities in design are being reassigned and redistributed. As traditional boundaries between design and use and designer and user dissolve, design is becoming more public. In the context of social technologies design is moving out into the wild.

INTRODUCTION
The issue of participation is revitalized in design and design research... (Binder et al., 2008 p.1).

From a design perspective social technologies present challenges to designers as well as opportunities. They enable new ways for people to participate in the design of products and services and provide new channels through which businesses can communicate with existing and potential users.

As the opening quote suggests, the issue of participation in design is receiving a massive influx of energy from a range of sources. Users are being re-cast as co-designers, co-creators and co-developers. Social technologies play a critical role in motivating this discourse.

There is widespread agreement that new approaches are required to take account of the diversifying contexts of technology design, of which social technologies are a part. However, we are still in the process of understanding and developing appropriate tactics and frameworks (Lee, 2008).

Practitioners and researchers alike are starting to encounter the limited capacity of existing Interaction Design methods to account for the new social spaces of technology design e.g., (Hart et al., 2008, Holzapfel, 2008, Isbister and Höök, 2009). In addition, success stories from social software companies that have taken a “throw it out there and see what happens approach” e.g., (Merholz, 2006, Porter, 2006) could be interpreted as a challenge to the value of early participation in design. Rather than suggesting a diminished role for user-focused methods, we take the position that it is as always, about asking what kinds of design methods are appropriate in this context.

In this paper we hope to contribute to a discussion on the nature of participation in the context of social technologies. The work of this paper is not to make defining statements, but rather to get ‘a lay of the land’. Robertson et al. (2006) suggest that questions about participation should be sought within the context in which particular technologies are designed, built and used. In this paper we ground our discussion through a review of current trends in research and industry. By observing current shifts in practice it is our intention to contribute to a better understanding of the nature of participation and design in the context of social technologies.

This is not an exhaustive review, but rather provides a filtered view of trends and concepts that we have observed in the course of our own research and that we hope will be useful to other researchers and practitioners. We draw our examples from a review of recent Participatory Design literature as well as industry case studies. We also draw broadly from recent HCI and design literature that addresses shifts in design practice related to social technologies.

The paper begins with a definition of social technologies and the changing landscape of design they represent. We then group and describe four perspectives on design in the context of social technologies, drawing on current trends in research and practice. Each of these enables participation in design in different ways. Some of them circumvent traditional user centred design methods while others extend them. Taking the four perspectives as references points, we then reflect on the changing shape of design. We draw particular attention to the ways in which roles and responsibilities in design are being reassigned and redistributed. We also identify some of the questions emerging out of these shifts and point to potential future work.
SOCIAL TECHNOLOGIES: A DEFINITION
Social technologies refer to the combinations of mobile and online tools and systems that enable and seek out participation and contributions by users. Examples include SMS, Facebook, MySpace, Flickr, Twitter, YouTube and Digg, personal blogs and discussion platforms as well as more localised community or campaigning sites. These systems are effectively containers or scaffolds that rely on participation and user driven contributions to take their form.

While we use the term social technologies in this paper, other popular phrases include: social software (Boyd, 2009a), social media (Näkki et al., 2008) and Web 2.0 (O'reilly, 2005). In qualifying the term social software boyd (2007b) states: “social software is about a movement, not simply a category of technologies... it’s certainly not complete and as a category, it’s difficult to make sense of its boundaries.”

The definition of social media provided by the Finish research institute VTT refers to social media as both a set of tools and a modus operandi (Heinonen and Halonen, 2007). Importantly both definitions re-enforce the dual emphasis on technologies and social practices.

We use the term social technologies here because it makes clear reference to the socio-technical nature of the phenomenon which we are attempting to describe. In addition, it can encompass combinations of mobile and/or online technologies, potentially indicating something broader than a single piece of software.

SOCIAL TECHNOLOGIES: A PHENOMENON
The phenomenon of social technologies can be characterised by greater social participation in mediated contexts (Boyd, 2007a). Terms such as user generated content (Pierson et al., 2008), crowdsourcing (Howe, 2008) and citizen media (Cruickshank and Evans, 2008) refer to emerging forms of social participation supported by social technologies.

Indeed the ease with which we can now connect, communicate, produce, share, replicate, locate and distribute information has had, and continues to have, a profound impact on our social, cultural and technological practices (Boyd, 2009a, Shirky, 2008). This transformation has been made possible by the wide availability and accessibility of technology. Most importantly this has included the shift in technology ownership from organisations and companies, to everyday people (Battarbee, 2003, Shirky, 2008).

For designers, social technologies become a tool with which we design, the subject of our design and the context within which we design. The emphasis on participation in social technologies challenges some of our traditional assumptions about the role of users and designers. It also exposes some of the limitations and assumptions about design embedded in our traditional models and methods.

CHALLENGES TO DESIGN
Designers attempting to apply conventional methods in the context of social technologies face various challenges. For example traditional contextual methods assume the ability to identify and access the context of use. But users of social technologies are diverse and geographically distributed (Bergvall-Kåreborn and Ståhlbröst, 2008); use is mobile, domestic and woven through complex, ongoing social contexts (Bødker, 2006, Isbister and Höök, 2009); and our users are potentially anonymous or unknown (Clement, 2008, Ehn, 2008). It is also quite possible that at the beginning of the design process there will be no clearly identifiable existing community of users, rather they have to be brought ‘into being’ as part of the project (Disalvo et al., 2007).

Furthermore, it is arguable that the variables of use are so complex, situated and dependent on the activities of others, that feedback about use only becomes meaningful in context. Current methods for prototyping and testing prior to the release of software may be inadequate for simulating the future contexts of use (Holzapfel, 2008). This could be understood as a question of fidelity. As Isbister & Höök note “We can’t rely on re-using pre-existing interface metaphors and strategies because there are too many new variables of use...” (2009 p.1).

Finally, User-Centred Design (UCD) methods, developed in the context of organisational and workplace technologies, cannot be expected to take into account the motivations for use to which social technologies are being put. This is particularly so when the purposes of these technologies are in themselves emergent; for example Flickr, SMS, Twitter and Facebook all perform radically different functions than those first envisioned by their designers.

Social technologies support behaviours like hanging around (Hart et al., 2008), messering around (Horst et al.), looking at, looking up, and keeping up (Joinson, 2008). Use is often prompted by emotional or/experiential factors such as a shared experience or shared interests (Battarbee and Kurvinen, 2003, Hess et al., 2008 ). The focus is on connecting and interacting around social objects (Engeström, 2005) and with other people, rather than with the system (Shirky, 2003). As Hart et al. (2008) highlight in their research, supporting these behaviours was not the motivation behind classic UCD yard-sticks such as Nielsen's 10 heuristics

It is these kinds of challenges that prompted the following review of how practitioners and researchers are responding to some of these issues, with particular emphasis on supporting participation in design. In the following section we review trends in current design practice that are emerging as a result of, and in response to, the participatory nature of social technologies.

DESIGN & PARTICIPATION
The categories and examples presented below are not exhaustive. Rather they are loose groupings that overlap and intersect. Together they represent four very high level perspectives on design in the context of social technologies. In the first two, Iterate It and Emerge It, social technologies are the subject of design. In the later two, Source It and Open It, social technologies are tools for design. We use a similar strategy for grouping and describing trends as was used in (Hagen et al., 2005).
Table 1 provides a summary of the approaches and examples, with a fuller description of each given in the following sections.

Table 1. Summary of approaches to design

**Iterate It**

Figure 1. Design is iterated through participation in use

In the **Iterate It** approach participation in design takes place through members of the community using and providing feedback on a system after its release. Changes in design may occur in response to user requests or as a result of observing how users appropriate or interact with the technology (Boyd, 2009b). Myspace (Boyd, 2007b), Netflix (Porter, 2006), Digg (Burka, 2008) and Slideshare (Sinha, 2007) are all major social web services that have developed and iterated their software in this way.

The **Iterate It** approach could be described as an incidental or naturally occurring form of participation resulting from the nature of social technologies and recent shifts in technology practices. Contributing factors are the emergence of web services (of which social technologies form a part), the prominence of open source software and a shift towards rapid or agile programming. In contrast to waterfall methods which have a big upfront design phase, the emphasis is on deploying early and continuing to rapidly add or remove features and fixes (O’Reilly, 2005). Users become co-developers and systems are treated as services not products (ibid).

Participation in the design iterations can be actively sought and planned for through methods such as beta releases (or even perpetual beta) (O’Reilly, 2005). There might also be other persistent online and formal feedback channels e.g., forums, Twitter accounts etc. Alternatively, they can occur in response to feedback that comes via a public backlash to company design decisions. Some ‘user-revolts’ have occurred on a historic scale, for example on Twitter (Corbin, 2009), Facebook (Spool, 2007) and Friendster (Boyd, 2005). In part as a result of these incidents, companies have come to better understand the need to work with their community on design changes. While an iterative approach might have initially been a technical response to the nature of webservices, in many cases this has transformed into more sophisticated forms of user participation and consultation post release.

**Emerge It**

Figure 2. Design emerges through participation

The **Emerge It** approach is also inspired by the philosophy of rapid development, but focuses on the use of experimental prototypes as the start point for exploring potential practices and uses (Botero and Saad-Sulonen, 2008, Redhead and Brereton, 2008, Twidale and Floyd, 2008). Design phases are blended into the implementation phases (Twidale and Floyd, 2008). For example Redhead & Brereton (2008) deployed an electronic-notice board prototype into a community. The prototype was then evolved *in situ*, in response to use and community feedback.

Patchwork prototyping takes a similar approach, relying on the combination of open source tools, local code and mash ups of existing services (Twidale and Floyd, 2008). Rudimentary prototypes are pulled together and immediately integrated and used as part of daily practice; an easy way of supporting real user participation in actual use (Twidale and Floyd, 2008). Importantly Jones et al. (2007) note that patchwork prototyping was observed as a phenomenon emerging out of practice, rather than being a method designed *a priori*. The researchers have since formed a research program around the approach.

Botero et al. (2008) also took a similar but deliberate ‘living research’ approach in the development of the Urban Mediator software. Seed prototypes were used in a co-discovery process with the community. Rather than undertaking traditional usability evaluations of isolated software components, Botero & Saad-Sulonen (2008) re-purposed existing software to create ‘concrete interventions’ that could be co-evolved.

Twidale and Floyd (2008) argue that such an approach only exists as a result of the current ecology of information technologies; social software lends itself to the deployment of simple prototypes that can be modified and evolved through feedback itself (Brereton and Buur, 2008). As predicted by Lievrouw (2006), re-configuration
of existing tools is becoming a key theme in design in the new media space.

Methodologically the *Emerge It* approach can also be linked to participatory design (Schuler and Namioka, 1993) and movements to support end-user development e.g (Fischer and Giaccardi, 2006). Embedded within the approach is an intention to develop the software *with* users, in use. Design is led by emergent community needs which become articulated and visible through use.

**Source It**

![Source](image)

**Figure 3. Initial design is (out) sourced to members of the public**

*Source It* emphasises a shift to public involvement in design ideation and innovation. The emphasis of *Source It* is on the open call format of crowdsourcing, a distributed problem-solving model (Brabham, 2008). Crowdsourcing makes use of the interests and effort of everyday people to achieve activities that might otherwise have been performed by suppliers or contractors (Howe, 2006).

For example T-shirt’s, sold by the company threadless.com, are designed by members of the public. Anyone can submit a design and those rated most highly by other online community members are put into production (Threadless, 2009). redesignme.com and WEPC are corporate versions that encourage design contributions from members of the public. Contributions may be discussed and rated by other members and potentially go on to influence future designs. Doritos and Converse have taken a similar approach leveraging the popularity of user generated video by having members of the public create product commercials (Howe, 2008).

Methodologically *Source It* approaches are tied to the open innovation business model which encourages businesses to seek ideas from external sources (Chesbrough, 2003). Open innovation promotes a form of co-design or co-creation with users and encourages companies to tap into user-driven innovation (Von Hippel, 2001). The scale and availability of social media is reducing the barriers to public participation in innovation processes. It is also disrupting and in some cases circumventing traditional interaction design process and practitioners.

**Open It**

![Open](image)

**Figure 4. Community participates throughout design**

*Open It* approaches also leverage the potential for crowdsourcing and open innovation enabled by social technologies. The emphasis of *Open It* is on the appropriation of social media as a way to open up the traditional UCD process to the community. Members of the public are invited to participate in and contribute to design, discussion, decision-making and evaluation. Asynchronous participation in design iterations such as ideation, cardsorting, wireframing and prototyping are mediated and facilitated through online platforms.

For example SOMED (Social media in the crossroads of physical, digital and virtual worlds) is a Finnish research project that has identified the potential to use social media to support open and distributed forms of participation in design (Näkki and Virtanen, 2007). Their online lab, Owela, makes use of various social media tools to enable participation in different phases of design (Näkki et al., 2008).

The community redesign of drupal.org (the website representing open source content management system Drupal) undertaken last year was a radical example of opening up the design process through the use of social technologies (Boulton, 2008). Boulton and Reichelt were contracted as designers to lead and facilitate the process, however the design itself needed to be open in keeping with the community ethos. Boulton and Reichelt worked with the community, experimenting with different ways to create an open design process.

While standard UCD methods were used, the nature of participation was quite different. Community members participated in mass, distributed, asynchronous, and remote design activities (e.g 70 card sorts in 2 days). In addition, rather than just giving feedback on designs, community members contributed their own wireframes. In order to facilitate collaboration and discussion around both concepts and process, Boulton and Reichelt used their personal blogs as well as platforms such as Twitter, Flickr, YouTube. They found that different tools significantly changed the scope of the conversation and allowed different kinds of input and conversation to happen (Reichelt, personal communication).

*Open It* examples are characterised by a commitment to enabling greater, more transparent participation in the design process through mediated means. *Open It* combines the commitment of participatory design (Schuler and Namioka, 1993) with the transparent and community driven approach embodied in the open source software movement. As Ehn states (2008), this movement is a growing source of inspiration for those concerned with participation and opening up design.

**DISCUSSION**

Each of the perspectives on design presented above envision and enable participation in different, potentially complementary ways. *Iterate It* and *Emerge It* emphasise design in use, while *Source It* and *Open It* suggest a more public design process. These trends and activities can be interpreted in various ways. In the following discussion we reflect on the shifting shape of design and the impact of corresponding changes to roles and responsibilities of designers and users. In doing so we draw together some of the questions being raised by the researchers and practitioners using these approaches.

**Relations of design and use**
Design approaches are relatively new and methods are still being investigated. The emergent nature of the approach means there is no clear outcome. Ways to articulate this as an opportunity rather than a risk, particularly in a commercial context, still need to be better understood.

**Roles and responsibilities**

Figure 7. Design activities redistributed

The notion that design activities take place in use highlights additional responsibilities for designers beyond the point at which designs reach communities (Binder et al., 2008). Figure 7 suggests a more continuous state of design as boundaries between phases collapse. While this might better reflect the nature of design and participation in this context, Ehn challenges us to consider the role of the professional designer and just how such ongoing relations might be managed (2008).

What shifts are necessary in our own practice to support these emerging forms of participation and collaboration? What new responsibilities, skills and roles do we take on as professional designers? According to Reichelt and Boulton their responsibilities extend to ‘skilling-up’ the user community to eventually take control of the design process (Reichelt, 2009). Brereton and Buur talk of “fostering appropriate engagements and championing and guarding core values that underlie the design philosophy” . (2008).

If as Ehn (2008) suggests we are moving beyond the traditional notion of a project, what kinds of contracts or periods of involvement are appropriate? How should we as design agencies and consultants model our services and relationships with clients and users? Commercial contexts could be informed by Fischer's (2008) suggestion that we rework the traditional “maintenance” model to better reflect the significant amount of design work that takes place once a system is released. Merholz (2006) argues that for design agencies who only consult on design in a ‘project by project’ capacity, the emergent nature of social technologies poses different challenges. In our own projects we have looked to research into community Participatory Design to better understand these issues e.g., (Karasti and Syrjänen, 2004).

Questions about the role of design and the skills required of designers are further complicated by the use of existing platforms as starting points. Traditionally designers have been responsible for the creation of a range of artefacts. In this case design becomes an act of reconfiguration and composition of existing software, rather than creation from scratch (Twidale and Floyd, 2008). Traditional boundaries between design and use are dissolving such that it is difficult at times to tell who, or where, design is being done (Balka, 2006).

**Design in the wild**

Another way in which the shape of design is changing is through the opening up of the design process. Design has
moved into the wild (Hutchins, 1995). *Source It* and *Open It* approaches support voluntary, mass, distributed participation in design by members of the public. Individual and community level discussion about design occurs within the context of people’s daily lives. Design is moving out from the studio and into what Lee (2008) describes as the concrete places that people live.

As this happens users are being assigned, or taking up, design activities once tasked to designers. For those facilitating such activities understanding how to motivate people to participate is becomes a key subject for research e.g. (Antikainen and Väätäjä, 2008). All of the approaches raise questions about the ownership over design and design decisions. According to the information available, Threadless.com appears to be the only example where participants control the final design output. It is also the simplest product, being a T-shirt. In all other cases professionals of some description are managing and filtering contributions. The motivations and design philosophies of the specialised ‘crowdsourcing’ companies is also something to consider. How equitable is the collaboration being proposed?

In *Open It* examples there was a commitment to enabling users to participate in design (rather than react to design). The work of (Hess et al., 2008, Reichelt, 2009) highlights the true scale of effort and time required for co-design and co-creation. In addition to new tools to facilitate communication with the community, professional designers also need new skills to avoid ‘design by committee’ when coordinating mass participation e.g., (Reichelt, 2009). Future work includes understanding both the potential roles played by users in these contexts and the development of strategies for managing these complex aspects of participation.

A deeper understanding of the commitments to participation embedded within the four different perspectives presented in this paper would also be critical to informing strategies around the value of various approaches at different times.

**CONCLUSION**

In this paper we have sought to investigate how practitioners and researchers are responding to the new landscape of social technologies. We have paid particular attention to how participation in design is being managed and supported. We have attempted to get a “lay of the land” through a review of current practice. In doing so we have identified four approaches to design and participation that respond to, or are enabled by, the nature of social technologies.

The overall effect of these shifts in design practice is an opening up of the design process. Design activities are being reassigned and redistributed, and design is becoming more public. Traditional boundaries between design and use and designer and user are beginning to dissolve as our roles and responsibilities are changing. While we have presented examples across all four perspectives significant work is still to be done in developing new methods and models of design that recognise both the ongoing nature of design as well as its increasingly public and collaborative nature.

Our intention in this paper was not to present an exhaustive review but rather to offer a filtered view of current trends in a way that we hope will be useful to other researchers and practitioners. Social technologies are promoting participation as a core concern in design and this is manifesting in a myriad of ways. For those of us committed to participatory design, this is very exciting!

**ACKNOWLEDGEMENTS**

We would like to give our sincere thanks to Digital Eskimo, Inspire Digital and their clients and stakeholders for the opportunity to work with them. We would also like to thank Dr Lian Loke, our fellow researchers in the IDHuP lab at UTS and our reviewers for their comments. We would also like to acknowledge Minna Isomursu, Pirjo Näkki, Andrea Botero and Leisa Reichelt for their time and generous discussion of issues that contributed to this paper.
